AI WORKFLOW DOCUMENT

WorkRadar: How AI Was Used to Research, Design and Build the Product

Tools, significant prompts, AI output, human modifications and key trade-offs

Author	Gopi Krishna	**Program**	AI Product Management (AIPM), AIR Tribe — Cohort 40
Version	1.0 (Final)	**Date**	27 October 2026
Related	PRD v3.0; UI/UX Specification v1.0; MVP web application	**Working mode**	AI as guide and builder; human as product owner and decision-maker

1 SUMMARY

WorkRadar was built end to end with AI in one working session of about four hours, covering all six assignment steps. AI handled research synthesis, first drafts, design specifications, screen generation and code. I owned the problem framing, the user and segment choice, the product principles, prioritisation and every acceptance decision. The most important human contribution was redirecting the AI four times: from an engineering-manager persona to a startup product manager, from "AI summarises everything" to a privacy-safe radar that links out, from colourful layouts to a formal document style, and from an open question list to locked decisions.

6 / 6
assignment steps completed with AI

7
AI tools and runtimes used

10
AI proposals changed by human decision

8
MVP screens built and tested

2 AI TOOLS USED

Tool	Used for	Assignment step
Claude (Anthropic), agentic workspace	Guide and builder: research, PRD, strategy, UX specification, MVP code, PDF generation	Steps 1–6
Claude web search	Secondary research: adoption data, interruption studies, API limits, competitors	Discovery PRD strategy
Claude Docs	Living research documents: Discovery & Feature Analysis; Solution Strategy & System Design; MVP Decisions, UX Spec & Task List	Discovery and planning
Claude design canvas	First high-fidelity screens (v1) for the five required screens	Step 2
Google Stitch	Final UI screens generated from AI-written, screen-by-screen prompts	Step 2
Claude artifact runtime	Hosting the MVP; live AI calls for the daily brief and item notes	Step 3
Headless Chromium (via Claude)	Rendering and visually checking every PDF and screen before delivery	Steps 1 2 4

3 SIGNIFICANT PROMPTS

Prompts are paraphrased and shortened; quoted phrases are my own words from the sessions.

#	Prompt (what I asked)	Why it mattered
1	Shared the full brief and six steps: *"you are acting as guide and doer... everything that we learned in PM course"*	Set the working model: AI drafts and builds; I direct and decide
2	Break down what Slack, Jira, GitHub and Email each do for a manager, merge overlapping features, separate exclusive and hard-to-build ones, apply MoSCoW, and decide whether to replace or aggregate	Produced the discovery analysis and the core decision: aggregate, never replace
3	Re-target to *"product managers... and that to a startups"* of about 50 people; size the market with TAM/SAM/SOM; run 5 Whys on the solution; prioritise with Kano, RICE, MoSCoW and HiPPO; define leading, lagging and guardrail metrics	Changed the user, the segment and the whole solution design
4	No AI summaries of private messages: show a prioritised list and *"a link to go back to that particular message"*; use tags like @blocker for the team	Created the link-out radar, the @pm tag convention and the privacy model
5	*"remove these 100 questions... list down what all tasks that are left"*	Moved the work from open questions to locked decisions, a task list and a UX spec
6	Shared reference dashboards; asked for status colours, calendar dots with hover, profile photos and titles, sorting per section, an undoable history, integrations and themes, with every colour defined	Produced the UI/UX specification and design tokens
7	*"give me the content for google stitch"*	Turned the specification into 12 copy-paste screen prompts with consistent mock data
8	*"give me the final mvp website"*	Built the working application from the specification

4 WHAT AI GENERATED

Output	Description
Research documents	Tool-by-tool function tables, merged feature matrix, adoption data with sources, competitor review, replace-versus-aggregate analysis and architecture diagram
Strategy and system design	Stakeholder map, TAM/SAM/SOM, seven merged manager jobs, integration pipeline and per-tool API constraints, AI failure modes, three 5 Whys iterations, Kano, RICE, MoSCoW, metrics and validation plan
PRD (four versions)	Two-page PRD covering all required sections plus OKRs, user stories, competitive landscape, risks and release plan
Ranking model	Score = Type + Urgency + Sender + Waiting + Impact (max 100) with P1/P2/P3 bands and worked examples
UX deliverables	Five v1 design screens, a seven-page UI/UX specification with colour tokens and screen specs, and twelve Google Stitch prompts
MVP application	Single-file web app: eight screens, 50 mock people, 32 mock items across five sources, ranking, filters, actions with undo, AI brief with fallback, themes

5 WHAT I MODIFIED (HUMAN DECISIONS)

AI first proposed	What I changed	Reason
Engineering manager as the primary user	**A product manager in a 50-person startup**	Narrower, testable segment; the PM coordinates across every team and tool
AI reads and summarises everything	**Rank only PM-addressed items; one-line extract plus a link to the exact message**	Privacy, lower cost and higher adoption; the PM replies in the original tool
AI detects blockers from chat text	**Team tags: @pm blocker, @pm decision, @pm sync, with AI only as a fallback**	Rules are more accurate and explainable than free-text detection
Design for an average day	**Design for the maximum: 50 people, about 60 items a day**	Load varies from 5 to 50 people; the busiest day must still work
Metrics focused on time saved	**Added "done for the day": priority items closed versus due, shown as a green, amber or red ring**	Gives the PM a clear daily finish line
Separate pages per item type	**One ranked list with type filters and per-type sort rules**	A PM's first question is "what first?", which only one ranking answers
Status shown only as priority	**Eight status colours, calendar dots with hover, profile photos and titles, team health**	The PM needs relationships and progress at a glance, not just tickets
Actions without history	**Activity Log with Undo and Restore; nothing is ever deleted**	The PM must see what they did today and recover from mistakes
100 open questions	**Locked decisions, a 12-task checklist and a UX specification**	Questions alone do not finish an MVP
Colourful card-style PDFs	**Formal document layout with numbered sections and page numbers**	Professional tone suited to a PRD submission

I also reviewed every AI output before accepting it: source links were opened and checked, PDFs were rendered and inspected page by page, and the MVP was tested on desktop and phone widths in light and dark themes.

6 KEY TRADE-OFFS

Decision	Chosen	Gained	Given up
Aggregate or replace	Aggregate: read from existing tools, link back	+ Zero change for the team; low build cost	− The PM still switches tools to reply
Mock or live data	Mock data shaped like real API events	+ Built in hours; full demo control	− No proof against real volumes yet (Version 2)
Rules or AI for ranking	Transparent formula; AI only for unclear items, brief and notes	+ Explainable ranks; works when AI fails	− Less adaptive than a learned model
Summaries or links	12-word extract and exact-message link	+ Privacy; trust; no stored message bodies	− Less context inside WorkRadar
Local actions or write-back	Done, Snooze, Assign saved in WorkRadar only	+ No sync conflicts or extra permissions	− Jira and GitHub are not updated automatically
Single-file app or full stack	One HTML file with browser storage	+ Opens anywhere; easy to submit	− No accounts, backend or multi-user state
Breadth or depth of research	Secondary research and assumptions, flagged as such	+ Speed within the assignment timeline	− No primary interviews yet; planned before the pilot

7 LESSONS LEARNED

1. **AI is fastest when the human frames the problem.** Each change of persona, segment or principle by me reshaped every downstream document within minutes.
2. **Specific prompts beat long prompts.** Real names, numbers and colours (for example, in the Stitch prompts) produced consistent screens across tools.
3. **AI defaults need product judgement.** The first drafts favoured summarising everything; privacy, cost and adoption required a narrower design.
4. **Verify, do not trust.** Rendering, page-count checks and source checks caught layout overflow, broken glyphs and unsupported claims before submission.
